Review

Extreme events in solutions of hydrostatic and non-hydrostatic climate models

BY J. D. GIBBON* AND D. D. HOLM

Department of Mathematics, Imperial College London, London SW7 2AZ, UK

Initially, this paper reviews the mathematical issues surrounding hydrostatic primitive equations (HPEs) and non-hydrostatic primitive equations (NPEs) that have been used extensively in numerical weather prediction and climate modelling. A new impetus has been provided by a recent proof of the existence and uniqueness of solutions of viscous HPEs on a cylinder with Neumann-like boundary conditions on the top and bottom. In contrast, the regularity of solutions of NPEs remains an open question. With this HPE regularity result in mind, the second issue examined in this paper is whether extreme events are allowed to arise spontaneously in their solutions. Such events could include, for example, the sudden appearance and disappearance of locally intense fronts that do not involve deep convection. Analytical methods are used to show that for viscous HPEs, the creation of small-scale structures is allowed locally in space and time at sizes that scale inversely with the Reynolds number.

Keywords: primitive equations; climate models; extreme events

1. Review of the hydrostatic and non-hydrostatic primitive equations

The hydrostatic primitive equations (HPEs) were adopted more than 80 years ago by Richardson, following the work of Bjerknes, as a model for large-scale atmospheric dynamics [1]. In various forms, they have been the foundation of most numerical weather, climate and global ocean circulation predictions for many decades. The HPEs govern incompressible, rotating, stratified fluid flows that are in hydrostatic balance. This balance is broken, however, in deep convection, which occurs in cloud formation, flows over mountains and vertical fluid entrainment by strong gravity currents. In this context, the hydrostatic approximation is the most reliable and accurate of all the assumptions made in applying them to operational numerical weather prediction (NWP), climate modelling and global numerical simulations of ocean circulation. The approximation arises from a

One contribution of 13 to a Theme Issue ‘Nonlinear phenomena, optical and quantum solitons’.
scale analysis of synoptic systems; see [2–18]. Basically, it neglects the vertical acceleration term in the vertical momentum equation. Physically, this enforces a perfect vertical force balance between gravity and the vertical pressure gradient force, which means that the pressure at a given location is given by the weight of the fluid above.

Until recently, the resolution of operational NWP models has been limited by computing power and operational time constraints on resolutions in which the hydrostatic approximation is almost perfectly valid. Operational forecasts therefore have relied mainly on hydrostatic models, which applied extremely well in numerical simulations of the global circulation of both the atmosphere and the ocean at the spatial and temporal resolutions that were available at the time. In parallel, the development of non-hydrostatic atmospheric models, which retain the vertical acceleration term and thus capture strong vertical convection, has also been pursued over a period of more than four decades, especially for mesoscale investigations of sudden storms. As computer systems have become faster and memory has become more affordable over the past decade, there has been a corresponding increase in the spatial resolution of both NWP and climate simulation models. This improvement has facilitated a transition from highly developed hydrostatic models towards non-hydrostatic models. Over the past decade, atmospheric research institutions have begun replacing their operational hydrostatic models with non-hydrostatic versions [14,15,17].

An impending ‘model upgrade’ may be tested by comparing the solution properties of the existing hydrostatic model at a new higher resolution with those of its non-hydrostatic alternative (non-hydrostatic primitive equations; NPEs). Using the fastest supercomputers available, global simulations of atmospheric circulation at resolutions of about 10 km in the horizontal (in the region of the hydrostatic limit) have recently been performed [19,20]. In the past, these simulations have been carried out using only hydrostatic models, as the non-hydrostatic versions were still under development. Perhaps not unexpectedly, the simulations at finer resolution found much more fine-scale structure than had been seen previously. More importantly, the smallest coherent features found at the previous coarser limits of resolution were no longer present at new finer resolutions, because the balance between nonlinearity and dissipation that had created them previously was no longer being enforced. Instead, it was being enforced at the new limits of resolution.

Consequently, an important conclusion from these primitive equation simulations has been that the transition from the existing hydrostatic model to its non-hydrostatic alternative, and the distinction between their solutions, will require, in both cases, a much better understanding of the formation of fine-scale frontal structures [20,21]. For discussions of the history of ideas in frontogenesis, see [22–25]. An example of fine-scale wind measurements is a ‘gust front’ found in figure 1 [16,26,27]. Gust fronts are indicated by ‘bow echoes’ on Doppler radar. These have been extensively observed and studied as the precursors of severe local weather.

In particular, the physical parametrizations in hydrostatic models are likely to require dramatic changes when simulated at new finer resolutions. Therefore, in order to obtain the full benefit of the potential increase in accuracy provided by such high spatial resolution when using the non-hydrostatic model, one must
first determine the range of solution behaviour arising at the finer resolution in the computations of the previous hydrostatic model [20]. Over relatively small domains, operational model resolutions in the atmosphere are in fact already beyond the hydrostatic limit. These models run at resolutions finer than 10 km, where convection is partially resolved (thus, inaccurately simulated) by non-hydrostatic models. However, convection can only be fully resolved at model resolutions of about two orders of magnitude finer, that is, about 100 m or less in the horizontal. It is therefore likely that, for many years to come, operational hydrostatic and non-hydrostatic models will function at resolutions where convection can only be partially resolved. Consequently, the distinction between hydrostatic and non-hydrostatic solution behaviour at these intermediate resolutions becomes paramount for the accuracy, predictability, reliability and physical interpretation of results in NWP.1

Against this background of renewed interest in the improvement of hydrostatic models and their newly acquired computability at higher resolution, this paper also reviews the development of new mathematical ideas introduced by Cao & Titi [28,29], who have proved the existence and uniqueness of strong solutions of the viscous HPEs.2 The corresponding regularity problem for viscous NPEs remains open.3 Ju [36] then built on the result of Cao & Titi to show that the viscous HPEs actually possess a global attractor, which means that the bounds are constants, although no explicit estimates were given. The status of results prior to the Cao & Titi proof [28,29] (e.g. the existence of weak solutions) can be found in the papers by Lions et al. [37–39] and Lewandowski [40]. Considering the technical difficulties of this new work, which has been solved on a cylindrical domain with Neumann-type boundary conditions on the top and

---

1The subtle difference is explained in §2 between what is known as the modellers’ HPE (MHPE) incorporated in many NWP and climate simulation models, and HPEs in cartesian geometry discussed here.

2See also Kobelkov [30–32] for a subsequent independent method of proof.

3This is closely related to the open regularity problem for the three-dimensional Navier–Stokes equations that has been solved only for very thin domains \(0 < \alpha_a \ll 1\) [33–35].
bottom, these results must be classed as a major advance. The significance of this result in establishing the existence and uniqueness of strong solutions of viscous HPEs is that no singularities of any type can form in the solutions.

The title and abstract of this review refer to the idea of ‘extreme events’; this term should not be interpreted in the present context in a statistical sense, but as the spontaneous appearance and disappearance of local, sudden, intermittent events with large gradients in the atmosphere or the oceans. These events would register as spatially localized, intense concentrations of vorticity and strain. Until the Cao–Titi result, a major open question in the subject had been whether these strong variations ultimately remained smooth? Now that we know that solutions of HPEs must remain smooth at every scale, the question still remains whether this smoothness precludes the existence of extreme events representing front-like structures: this would be manifested in jumps or steep gradients in double-mixed derivatives such as $|\partial^2 u_1/\partial x_2 \partial x_3|$ or $|\partial^2 u_2/\partial x_1 \partial x_3|$ within finite regions of space–time. The ultimate aim is to explain fine-structure processes such as those that occur in fronto-genesis; see the work of Hoskins [23,25] and Hoskins & Bretherton [24] for general background on this phenomenon.

Section 3 of this paper seeks to address this problem from a mathematical angle. The regularity of solutions opens a way of showing that front-like events are possible at very fine scales. The method used is to search for fine structure by examining the local behaviour of solutions in space–time. The conventional approach to PDEs has been to prove boundedness of norms that, as volume integrals, tend to obscure the fine structure of a solution. The idea was first used [under strong regularity assumptions] to estimate intermittency in Navier–Stokes turbulence [41]. The mathematical approach is to show that solutions of HPEs may be divided into two space–time regions $\mathbb{S}^+$ and $\mathbb{S}^-$. If $\mathbb{S}^-$ is non-empty, then very large lower bounds on double-mixed derivatives of components of the velocity field $(u_1, u_2, u_3)$ such as $|\partial^2 u_1/\partial x_2 \partial x_3|$ or $|\partial^2 u_2/\partial x_1 \partial x_3|$ may occur within $\mathbb{S}^-$. These large point-wise lower bounds on second-derivative quantities represent intense accumulation in the $(x_1, x_3)$- and $(x_2, x_3)$-planes, respectively. Clearly, if solutions of great intensity were to accumulate in regions of the space–volume, this could only be allowed for finite times, in local spatial regions. Thus, one would see the spontaneous formation of a front-like object localized in space that would only exist for a finite time. More specifically, the lower bounds within $\mathbb{S}^-$ referred to above are a linear sum of $\mathcal{R}_{u_{\mathrm{hor}}}^6$, $\mathcal{R}_{u_1}^6$ and $\mathcal{R}_{u_3}^6$, where $\mathcal{R}_{u_{\mathrm{hor}}}$ and $\mathcal{R}_{u_3}$ are local Reynolds numbers. That is, they are defined using the local space–time values of $u_{\mathrm{hor}}(x_1, x_2, x_3, \tau) = (u_{1\tau}^2 + u_{2\tau}^2)^{1/2}$ and the vertical velocity $u_3 = u_3(x_1, x_2, x_3, \tau)$. Likewise, $\mathcal{R}_{a, T}$ is a local Rayleigh number, defined using the local temperature $T(x_1, x_2, x_3, \tau)$. In contrast, $Re$ is the global Reynolds number. These lower bounds within the $\mathbb{S}^-$-regions can be converted into lower bounds on the two point-wise inverse length scales $\lambda_H$,

$$L\lambda_H^{-1} > c_{u_{\mathrm{hor}}}(\mathcal{R}_{u_{\mathrm{hor}}} + c_{u_1} \mathcal{R}_{u_1} + c_{1, T}\mathcal{R}_{a, T} + c_{2, T} Re^{2/3} \mathcal{R}_{a, T}^{1/3} + \text{forcing.} \quad (1.1)$$

Unfortunately, the methods used for the HPE do not extend to the three-dimensional Navier–Stokes equations; although HPEs had been thought to be the more difficult of the two. See Lions et al. [37–39].
The term $R_{u_3} \sim O(\varepsilon)$ is negligible compared with $R_{u_{hor}}$. If such a result were valid for NPEs, it would be this vertical term that would be restored. The estimate for $\lambda_H$ in equation (1.1) is of the order of a metre or less, at high Reynolds numbers. Our interpretation of this very small length is not that it is necessarily the thickness of a front, but that it may refer to the smallest scale of features within a front. If an equivalent result for NPEs could be found, then the estimate of the length scale $\lambda_N$ (say) would probably be considerably smaller than that for $\lambda_H$.

2. Formulating the primitive equations

In what follows, dimensionless coordinates are denoted by $(x, y, z, t)$. These are related to dimensional variables $(x_1, x_2, x_3, t)$ through the horizontal length scale $L$ and the vertical length scale $H$. Table 1 gives the various standard definitions. Table 2 gives the notation concerning dimensionless and dimensional variables and some of the relations between them.

Dimensionless versions of both the HPE and NPE are expressed in terms of a set of velocity vectors based on the two horizontal velocities $(u, v)$ and the vertical velocity $w$. These form the basis for the three-dimensional vector\(^5\)

$$V(x, y, z, t) = (u, v, \varepsilon w),$$

satisfying $\text{div} \, V = 0$ or $u_x + v_y = -\varepsilon w_z$. The hydrostatic velocity vector is defined by

$$v = (u, v, 0),$$

and the non-hydrostatic velocity vector by

$$v = (u, v, \alpha^2 \varepsilon w),$$

where $\alpha$ is the aspect ratio defined in table 3. Neither $v$ nor $v$ are divergence free.

The HPEs that are studied in this paper should be compared with the modellers’ HPE (MHPE) used by Richardson and incorporated in many NWP and climate simulation models to this day [14–17]. While the MHPEs are written for a compressible fluid in the non-Euclidean geometry of a shallow atmosphere (i.e. the domain of flow is a spherical shell of constant radius, although vertical extent and motion are allowed), the HPEs as laid out in §2a are written for an incompressible fluid in a Cartesian geometry. The ‘incompressibility’ of hydrostatic models appears when pressure is used as a vertical coordinate. Hoskins & Bretherton [24] used a function of pressure to define a vertical coordinate that delivers the HPEs for a compressible fluid that are nearly isomorphic to those for an incompressible fluid when ordinary height is used as the vertical coordinate. They then introduced an approximation in the continuity equation that made the near-isomorphism exact. The resulting HPEs have frequently been used in theoretical studies and have led to many important results, but they are not identical to the MHPEs that numerical modellers since Richardson have typically used.

\(^5\)Comparing with the notation in Holm [9], $(u, v) \equiv u_2$, while $V \equiv u_3$ and $v \equiv v_3$.

There is no evolution equation for the vertical velocity $w$, which lies in both $V \cdot \nabla_3$ and the incompressibility condition $\text{div } V = 0$, but, in principle, $w$ can be recovered by a partial $z$-integration of the latter constraint as in Cao & Titi [29]. The $z$-derivative of the pressure field $p$ and the dimensionless temperature $\Theta$ enter the problem through the hydrostatic equation

$$a_0 \Theta + p_z = 0,$$

where $a_0$ is defined in Table 1. The hydrostatic velocity field $v = (u, v, 0)$ appears when equations (2.4)–(2.6) are combined,

$$\varepsilon \left( \frac{\partial}{\partial t} + V \cdot \nabla_3 \right) v + k \times v + a_0 k \Theta = \varepsilon Re^{-1} \Delta_3 v - \nabla_3 p,$$

and taken in tandem with the incompressibility condition, $\text{div } v = -\varepsilon w_z$. The dimensionless temperature $^6 \Theta$, with a specified heat source/sink term $q(x, y, z, t)$, satisfies

$$\left( \frac{\partial}{\partial t} + V \cdot \nabla_3 \right) \Theta = (\sigma Re)^{-1} \Delta_3 \Theta + q.$$

The chosen domain is a cylinder of height $H$ ($0 \leq z \leq H$) and radius $L$, designated as $C(L, H)$. In terms of dimensionless variables, boundary conditions are taken to be as follows.

— On the top and bottom of the cylinder $z = 0$ and $z = H$, the normal derivatives satisfy $u_z = v_z = \Theta_z = 0$ together with $w = 0$. This is appropriate for the atmosphere where the heat source/sink term $q(x, y, z, t)$ in equation (2.8) is dominant. Ideally, in the case of the ocean, as in

$^6$Note that we use the upper case $\Theta$ for the temperature to avoid confusion with lower case $\theta$, which is conventionally used for the potential temperature.
The key feature for HPEs in the following is the use of enstrophy (i.e. vorticity squared) rather than kinetic energy as a quadratic measure of motion. This means that the pressure gradient is excluded from the dynamics at an early stage and, more importantly, that the analysis is immediately in terms of spatial derivatives of velocity components rather than the components themselves. In contrast, earlier approaches based on the available potential energy include the pressure field until a global spatial integral removes it, and this has made local results more difficult to reach. In addition, energy arguments deliver results about attainable velocities not about velocity gradients.

The vorticity \( \zeta = \text{curl } \mathbf{v} \) is specifically given by
\[ \zeta = \text{curl } \mathbf{v} = -i u_z + j u_z + k (v_x - u_y). \] (2.9)
This contains the same \( k \)-component as the full three-dimensional vorticity \( \omega = \nabla_3 \times \mathbf{V} \), but with the \( w \)-terms missing from the other components. The relation between \( \zeta \) and \( \omega \) gives rise to a technically important relation,
\[ -\mathbf{V} \cdot \nabla_3 \mathbf{v} = \mathbf{V} \times \zeta - \frac{1}{2} \nabla_3 (u^2 + v^2). \] (2.10)
Taking the curl of equation (2.7) gives
\[ \varepsilon \frac{\partial \zeta}{\partial t} = \varepsilon Re^{-1} \Delta_3 \zeta + \varepsilon \text{curl}(\mathbf{V} \times \zeta) - \text{curl}(k \times \mathbf{v} + a_0 k \Theta). \] (2.11)
This relation forms the basis of the proof of theorem 3.1 in §3.

\( b \) Non-hydrostatic primitive equations

The NPEs restore vertical acceleration so that, in contrast to equation (2.6), the equation for \( w \) reads
\[ \varepsilon_a^2 \varepsilon^2 \left( \frac{\partial}{\partial t} + \mathbf{V} \cdot \nabla_3 \right) w + a_0 \Theta + p_z = \varepsilon Re^{-1} \Delta_3 w. \] (2.12)
Using the definition of \( \mathbf{v} \) in equation (2.3) and putting equation (2.12) together with equations (2.4) and (2.5), we find
\[ \varepsilon \left( \frac{\partial}{\partial t} + \mathbf{V} \cdot \nabla_3 \right) \mathbf{v} + k \times \mathbf{v} + a_0 k \Theta = \varepsilon Re^{-1} \Delta_3 \mathbf{v} - \nabla_3 p. \] (2.13)
The equation for the temperature (2.8) remains the same. Thus, NPEs are a version of the three-dimensional Navier–Stokes–Boussinesq equations on a non-cubical domain; note the difference in scaling between \( \mathbf{V} = (u, v, \varepsilon w) \), \( \mathbf{v} = (u, v, \alpha_2^2 \varepsilon w) \) and a standard Navier–Stokes \( (u, v, w) \) operating on a cubical domain. In contrast to the hydrostatic case where regularity has been established with
realistic Neumann-type boundary conditions on the top of a cylinder, several major open questions remain in the non-hydrostatic case.

— Given the connection between NPEs and the three-dimensional Navier–Stokes equations, it is hardly surprising that no proof yet exists for the regularity of the NPE (2.13). Their prognostic equation for $w$ brings NPEs much closer to the three-dimensional Navier–Stokes equations for a rotating stratified fluid than HPEs, in which $w$ is diagnosed from the incompressibility condition. While regularity properties for Navier–Stokes fluids on very thin domains ($0 < \alpha_a \ll 1$) have been established [33,34], the general regularity problem remains open.

— The boundary integrals for HPEs estimated on the top and bottom of the cylinder $C(H, L)$ are also problematic for NPEs. Whereas the vorticity $\zeta$ in the hydrostatic case has only terms $uz$ and $vz$ in the horizontal components, which are specified on the top and bottom of $C(H, L)$, the non-hydrostatic vorticity

$$w = \text{curl } \mathbf{v}$$

(2.14)

also includes $wx$ and $wy$ terms, which are not specified.

Similar to equation (2.10), there exists a technical relation between $V$, $\mathbf{v}$ and $\mathbf{w}$,

$$-V \cdot \nabla_3 \mathbf{v} = V \times \mathbf{w} - \frac{1}{2} \nabla_3 [w_3^2 - \varepsilon^2 w^2 (\alpha_a^2 - 1)^2],$$

(2.15)

so the curl operation on equation (2.13) gives

$$\varepsilon \frac{\partial \mathbf{w}}{\partial t} = \varepsilon \text{Re}^{-1} \Delta_3 \mathbf{w} + \varepsilon \text{curl}(V \times \mathbf{w}) - \varepsilon \text{curl}(k \times \mathbf{v} + a_0 k \Theta),$$

(2.16)

without involving pressure terms.

To address the influence of the material derivative in equation (2.12), typical values of $\alpha_a^2 \varepsilon^2$ can be determined. Typical observed values for mid-latitude synoptic weather and climate systems are

$$\alpha_a = \frac{H}{L} \approx \frac{10^4 \text{ m}}{10^6 \text{ m}} \approx 10^{-2},$$

$$W \frac{U}{10^{-2} \text{ ms}^{-1}} \approx 10^{-3}$$

(2.17)

and

$$\varepsilon = \frac{U}{(f_0 L)} \approx \frac{10 \text{ ms}^{-1}}{(10^{-1} \text{s}^{-1} 10^6 \text{ m})} \approx 10^{-1}.$$

For mid-latitude large-scale ocean circulation, the corresponding numbers are

$$\alpha_a = \frac{H}{L} \approx \frac{10^3 \text{ m}}{10^5 \text{ m}} \approx 10^{-2},$$

$$W \frac{U}{10^{-3} \text{ ms}^{-1}} \approx 10^{-2}$$

(2.18)

and

$$\varepsilon = \frac{U}{(f_0 L)} \approx \frac{10^{-1} \text{ ms}^{-1}}{(10^{-1} \text{s}^{-1} 10^5 \text{ m})} \approx 10^{-2}.$$
Thus, for these typical conditions, $a_2 a_3^2 \approx 10^{-3} - 10^{-6} \ll 1$, so the hydrostatic approximation can be expected to be accurate in calculations of either synoptic weather and climate, or large-scale ocean circulation at mid-latitude; see the discussion in Holton [7] regarding dynamical balances.

3. Extreme events and their interpretation

The proof of global existence and uniqueness of solutions of HPEs by Cao & Titi guarantees that at each point in space–time, a unique solution exists [28,29,36]. This result can be exploited to prove theorem 3.1 and from this to consider the idea of extreme events.

Consider the arbitrary positive constants $0 < \delta_1, \delta_2 < 1$ chosen such that

$$2\delta_3 = 1 - \frac{3}{4} \delta_1 - \delta_2 > 0. \quad (3.1)$$

These are used to define a hydrostatic forcing function $F(H(Q))$,

$$F_H(Q) = \epsilon^{-2} \left( \delta_2 + \frac{1}{2\delta_2} \right) Re^2 R_{\text{elev}}^2 + \frac{\sigma}{6\delta_3 T_0^2 \omega_0^2} Re|Q|^2. \quad (3.2)$$

The spatially global quantity $\mathcal{H}(t)$

$$\mathcal{H}(t) = \int_{V} (Re^3 |\xi|^2 + Re|\Theta_x|^2) \, dV \quad (3.3)$$

is now used in the proof of the following theorem.

**Theorem 3.1.** In $C(H, L)$ over some chosen time interval $[0, \tau_*]$, the space–time 4-integral satisfies

$$\int_{0}^{\tau_*} \int_{V} \left\{ -\beta_1 \left[ |\nabla_2 Q_4|^2 + \alpha_a^2 \left| \frac{\partial^2 u_1}{\partial x_2 \partial x_3} \right|^2 + \alpha_a^2 \left| \frac{\partial^2 u_2}{\partial x_1 \partial x_3} \right|^2 \right] \\
- \beta_2 \alpha_a^2 |\nabla_3 T_{x_3}|^2 + \beta_1 \alpha_a^2 \mathcal{R}_{\text{elev}}^6 + \beta_1 \alpha_a^2 \mathcal{R}_{\text{elev}}^6 + \beta_1 \mathcal{R}_{\text{elev}}^6 + \beta_1 \mathcal{R}_{\text{elev}}^6 + \beta_2 \mathcal{R}_{\text{elev}}^6 + \beta_2 \mathcal{R}_{\text{elev}}^6 \\
+F_H(Q) + \frac{1}{2} \mathcal{V}_*^{-1} \mathcal{H}(0) \right\} \, dx_1 \, dx_2 \, dx_3 \, d\tau > 0, \quad (3.4)$$

where the coefficients were given in table 3.

**Remark 3.2.** The proof in §3a shows that the right-hand side of equation (3.4) is, in fact, $1/2 \mathcal{H}(\tau_*)$. Because solutions of the HPE are regular, this is bounded above for all values of $\tau_*$. However, it has a lower bound of zero, which, although not necessarily a good lower bound, is uniform in $\tau_*$. Regularity of solutions is also a necessity in order to extract point-wise functions from within the 4-integral in equation (3.4).

**Remark 3.3.** Of course, any integral of the form $\int \int (A - B) \, dV \, dt > 0$ trivially indicates that there must be regions of space–time where $A > B$ but, potentially, there could also be regions where $A \leq B$. Such integrals are common, particularly energy integrals, and in most cases, the information gained is of little interest. In the case of equation (3.4), however, the proof in §3a is based on one gradient

*Phil. Trans. R. Soc. A* (2011)
higher than energy, such as the mixed second derivatives, and requires some effort
to manipulate it into a form that produces sensible and recognizable physics—e.g.
the horizontal Reynolds number and Rayleigh numbers.

From equation (3.4), we conclude that

— there are regions of space–time $S^+ \subset \mathbb{R}^4$ on which

\[
\beta_1 \left( |\nabla_2 Q_3|^2 + \alpha_a^2 \left| \frac{\partial^2 u_1}{\partial x_2 \partial x_3} \right|^2 + \alpha_a^2 \left| \frac{\partial^2 u_2}{\partial x_1 \partial x_3} \right|^2 \right) + \beta_2 \alpha_a^2 |\nabla T_{x_3}|^2
\]

\[
< \beta_{\text{inor}} R_{\text{inor}}^6 + \beta_{u_1} R_{u_1}^6 + \beta_{1,T} R_{a,T}^6 + \beta_{2,T} R e^4 R_{a,T}^2 + F_H(Q)
\]

+ $O(\tau_6^{-1})$ and

\[\text{(3.5)}\]

— potentially, there are also regions of space–time $S^- \subset \mathbb{R}^4$ on which

\[
\beta_1 \left( |\nabla_2 Q_3|^2 + \alpha_a^2 \left| \frac{\partial^2 u_1}{\partial x_2 \partial x_3} \right|^2 + \alpha_a^2 \left| \frac{\partial^2 u_2}{\partial x_1 \partial x_3} \right|^2 \right) + \beta_2 \alpha_a^2 |\nabla T_{x_3}|^2
\]

\[
\geq \beta_{b_{\text{hor}}} R_{b_{\text{hor}}}^6 + \beta_{u_1} R_{u_1}^6 + \beta_{1,T} R_{a,T}^6 + \beta_{2,T} R e^4 R_{a,T}^2 + F_H(Q)
\]

+ $O(\tau_6^{-1})$.

\[\text{(3.6)}\]

It must be stressed that there is no information here about the nature of the two
sets $S^{\pm}$; the 4-integral in equation (3.4) above yields no more information
other than the possibility of a non-empty set $S^-$ existing. It says nothing about the
spatial or temporal statistics of the subsets of $S^-$ (which may have a very sensitive
$\tau_6$ dependence), nor does it give any indication of their topology. These results,
however, are consistent with the observations of fronts in the atmosphere where
large second gradients appear spontaneously in confined spatial regions, often
disappearing again in an equally spontaneous manner. This behaviour would also
be consistent with $S^-$ being a disjoint union of subsets, although no details can
be deduced from equation (3.4).

To illustrate the nature of a front, very large values of double-mixed derivatives
are required in local parts of the flow, as envisaged in the early and pioneering
work of Hoskins [23,25]. For instance, very large values of $|\partial^2 u_1/\partial x_3 \partial x_2|^2$ or
$|\partial^2 u_2/\partial x_3 \partial x_1|^2$ would represent intense accumulation in the $(x_1, x_3)$- and $(x_2, x_3)$-
planes, respectively.

The large lower bounds in theorem 3.1 can be interpreted in terms of a length
scale. To achieve this, define the point-wise inverse length scale $\lambda_H^{-1}$ such that

\[
(L \lambda_H^{-1})^6 = L^2 \omega_0^{-2} \left( |\nabla_2 Q_3|^2 + \alpha_a^2 \left| \frac{\partial^2 u_1}{\partial x_2 \partial x_3} \right|^2 + \alpha_a^2 \left| \frac{\partial^2 u_2}{\partial x_1 \partial x_3} \right|^2 \right)
\]

\[
+ \alpha_a^2 \beta_2 \beta_1^{-1} L^4 |\nabla_3 T_{x_3}|^2 T_0^{-2}.
\]

\[\text{(3.7)}\]

\[7\text{The point-wise local length scale $\lambda_H^{-1}$ is formed in the same dimensional manner as the Kraichnan length $\ell_k$, namely, from a combination of the palenstrophy $|\nabla \omega|^2$ and the viscosity $\nu$ given by $\ell_k^{-2} = \nu^{-2} |\nabla \omega|^2$.}\]
The sixth powers on the right-hand sides of theorem 3.1 give results within $S^-$,

$$L_H^{-1} > c_{u_{h_{	ext{or}}}} R_{u_{h_{	ext{or}}}} + c_{u_3} R_{u_3} + c_{1,T} R_{a,T} + c_{2,T} Re^{2/3} R_3^{1/3} + \text{forcing}, \tag{3.8}$$

where the coefficients $c_{u_{h_{	ext{or}}}}, c_{u_3}$ and $c_{1,T}$ can be calculated from theorem 3.1; indeed, the term $R_{u_3}$ can be ignored as the vertical velocity $u_3 \sim O(\epsilon)$. Equation (3.8) can be interpreted as a lower bound on the inverse length scale of the smallest feature in a front. As already noted, no information is available on any statistics nor on the shape and size of subsets of $S^-$.

\[(a) \text{ Proof of theorem 3.1}\]

\[\text{(i) The evolution of the enstrophy}\]

The equation for the HPE enstrophy $\zeta$ in equation (2.11) is now considered on the cylinder $C(H,L)$, with the boundary conditions $u_z = v_z = w = 0$ on the top and bottom, but with periodic side-wall conditions,

$$\frac{1}{2} \epsilon \frac{d}{dt} \int_V |\zeta|^2 \, dV = \epsilon Re^{-1} \int_V \zeta \cdot \Delta_3 \zeta \, dV + \epsilon \int_V \zeta \cdot \text{curl}(V \times \zeta) \, dV - \int_V \zeta \cdot \text{curl}(k \times \nu + a_0 k \Theta) \, dV. \tag{3.9}$$

The notation in the rest of the paper is

$$\|f\|_p = \left( \int_V |f|^p \, dV \right)^{1/p}. \tag{3.10}$$

Note that in estimating the integrals in equation (3.9), a standard vector identity and the divergence theorem are used in which a surface integral naturally appears each time. However, on the cylinder top and bottom,

$$k \times \zeta = 0 \quad \text{on } z = 0, H. \tag{3.11}$$

This and the side-wall periodic boundary conditions make zero all the surface integrals that appear from the divergence theorem.

Considering equation (3.9) term by term, the first is $(\text{div } \zeta = 0)$

$$\int_V \zeta \cdot \Delta_3 \zeta \, dV = - \int_V \zeta \cdot \text{curl} \text{ curl } \zeta \, dV = - \int_V |\text{curl } \zeta|^2 \, dV. \tag{3.12}$$

The second integral on the right-hand side of equation (3.9)

$$\int_V \zeta \cdot \text{curl}(V \times \zeta) \, dV = \int_V \text{curl } \zeta \cdot (V \times \zeta) \, dV, \tag{3.13}$$

and so

$$\int_V \zeta \cdot \text{curl}(V \times \zeta) \, dV \leq \|\text{curl } \zeta\|_2 \|V\|_6 \|\zeta\|_3. \tag{3.14}$$

Thirdly,

$$\int_V \zeta \cdot \text{curl}(k \times \nu + a_0 k \Theta) \, dV = \int_V \text{curl } \zeta \cdot (k \times \nu + a_0 k \Theta) \, dV. \tag{3.15}$$
Thus, equation (3.9) can be rewritten as

\[
\frac{1}{2} \varepsilon \frac{d}{dt} \int_{V} |\xi|^2 \, dV \leq -\varepsilon Re^{-1} \int_{V} |\text{curl} \, \xi|^2 \, dV + \varepsilon \|\text{curl} \, \xi\|_2 \|V\|_6 \|\xi\|_3
\]

\[-\int_{V} (\text{curl} \, \xi) \cdot (k \times \mathbf{v} + a_0 k \Theta) \, dV
\]

\[\equiv -\varepsilon Re^{-1} \int_{V} |\text{curl} \, \xi|^2 \, dV + T_1 + T_2 + T_3, \quad (3.16)
\]

where

\[T_1 = \varepsilon \|\text{curl} \, \xi\|_2 \|V\|_6 \|\xi\|_3 \quad (3.17)
\]

and

\[T_2 = -\int_{V} (\text{curl} \, \xi) \cdot (k \times \mathbf{v}) \, dV \quad \text{and} \quad T_3 = -a_0 \int_{V} (\text{curl} \, \xi) \cdot (k \Theta) \, dV. \quad (3.18)
\]

Before estimating \(T_1\), \(T_2\) and \(T_3\), we prove the following lemma.

**Lemma 3.4.** In the cylinder \(C(H, L)\),

\[\|\xi\|_3 \leq 3^{1/2} \|\text{curl} \, \xi\|_2^{1/2} \|\mathbf{v}\|_6^{1/2}. \quad (3.19)
\]

**Proof.** Consider

\[\int_{V} |\xi|^3 \, dV = \int_{V} \xi \cdot (\xi \xi) \, dV
\]

\[= \int_{V} \mathbf{v} \cdot \text{curl} \, (\xi \xi) \, dV - \int_{S} \text{div} \, (\xi (\mathbf{v} \times \xi)) \, dS
\]

\[= \int_{V} \mathbf{v} \cdot (\xi \text{curl} \, \xi + (\nabla_3 \xi) \times \xi) \, dV - \int_{S} \text{div} \, (\xi (\mathbf{v} \times \xi)) \, dS. \quad (3.20)
\]

The surface integral is zero because \(k \times \xi = 0\) on the cylinder top and bottom. A vector identity

\[\nabla_3 \xi = \frac{1}{2} (\xi)^{-1} \nabla_3 (\xi \cdot \xi) = \hat{\xi} \cdot \nabla_3 \xi + \hat{\xi} \times \text{curl} \, \xi \quad (3.21)
\]

allows us to write

\[\text{curl} \, (\xi \xi) = \xi \text{curl} \, \xi + (\xi \times \text{curl} \, \xi) \times \hat{\xi} - \xi \times (\hat{\xi} \cdot \nabla_3 \xi), \quad (3.22)
\]

so we conclude that

\[\int_{V} |\xi|^3 \, dV = \int_{V} \mathbf{v} \cdot (\xi \text{curl} \, \xi + (\xi \times \text{curl} \, \xi) \times \hat{\xi} - \xi \times (\hat{\xi} \cdot \nabla_3 \xi)) \, dV. \quad (3.23)
\]

Using a Hölder inequality, it is then found that

\[\int_{V} |\xi|^3 \, dV \leq 3 \|\text{curl} \, \xi\|_2 \|\xi\|_3 \|\mathbf{v}\|_6, \quad (3.24)
\]

giving the result (3.19).
Lemma 3.5. Within the cylinder $C(L, H)$, $T_1$, $T_2$ and $T_3$ are estimated as
\[
|T_1| \leq \frac{3}{4} \delta_1 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{3 \varepsilon}{4 \delta_1^2} R e^3 (2 \|V\|_6^6 + \|v\|_6^6), \tag{3.25}
\]
for any $\delta_1 > 0$. Moreover, for any $\delta_2 > 0$ and $\delta_2 > 0$,
\[
|T_2| \leq \frac{1}{2} \delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{1}{2} \delta_2^{-1} \varepsilon^{-1} R e \|v\|_2^2 \tag{3.26}
\]
and
\[
|T_3| \leq \frac{1}{2} \delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{a_0^2}{2 \delta_2} R e \|\Theta\|_2^2. \tag{3.27}
\]

Proof. In the following, the $\delta_i > 0$ are constants introduced by a series of Young’s inequalities.

— using lemma 3.4, $T_1$ can be written as
\[
T_1 = \varepsilon \|\text{curl } \zeta\|_2 \|V\|_6 \|\zeta\|_3 \tag{3.28}
\]
\[
\leq \varepsilon \|\text{curl } \zeta\|_2 \|V\|_6 \times 3^{1/2} \|\text{curl } \zeta\|_2^{1/2} \|v\|_6^{1/2}
\]
\[
\leq (\delta_1 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2)^{3/4} (9 \varepsilon \delta_1^{-3} R e^3 \|V\|_6^6)^{1/6}
\]
\[
\times (9 \varepsilon \delta_1^{-3} R e^3 \|v\|_6^6)^{1/12}
\]
\[
\leq \frac{3}{4} \delta_1 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{3 \varepsilon}{4 \delta_1^3} R e^3 \left(2 \|V\|_6^6 + \|v\|_6^6\right), \tag{3.29}
\]

— from equation (3.18), $T_2$ can be estimated as
\[
|T_2| \leq \|\text{curl } \zeta\|_2 \|v\|_2 = (\delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2)^{1/2} (\delta_2^{-1} \varepsilon^{-1} R e \|v\|_2^2)^{1/2}
\]
\[
\leq \frac{1}{2} \delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{1}{2} \delta_2^{-1} \varepsilon^{-1} R e \|v\|_2^2, \quad \text{and} \tag{3.30}
\]

— from equation (3.18), and using the same constant $\delta_2$, $T_3$ is estimated as
\[
|T_3| \leq a_0 \|\text{curl } \zeta\|_2 \|\Theta\|_2 = (\delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2)^{1/2} \left(\frac{a_0^2}{\delta_2 \varepsilon} R e \|\Theta\|_2^2\right)^{1/2}
\]
\[
\leq \frac{1}{2} \delta_2 \varepsilon R e^{-1} \|\text{curl } \zeta\|_2^2 + \frac{a_0^2}{2 \delta_2 \varepsilon} R e \|\Theta\|_2^2, \tag{3.31}
\]
as advertised.

Returning to equation (3.9), a division by $\varepsilon$ and a gathering term gives
\[
\frac{1}{2} \frac{d}{dt} \int_{\mathcal{V}} |\zeta|^2 \, dV \leq - \left(1 - \frac{3}{4} \delta_1 - \delta_2\right) R e^{-1} \int_{\mathcal{V}} |\text{curl } \zeta|^2 \, dV
\]
\[
+ \frac{3}{4 \delta_1^3} R e^3 (2 \varepsilon^6 \|w\|_6^6 + 3 \|v\|_6^6) + \frac{1}{\varepsilon^2} \left(\delta_2 + \frac{1}{2 \delta_2}\right) R e \|v\|_2^2
\]
\[
+ \frac{a_0^2}{2 \varepsilon^2 \delta_2} R e \|\Theta\|_2^2. \tag{3.32}
\]
The following lemma relates $\int_{V} |\text{curl}\, \zeta|^2 \, dV$ to sums of squares.

**Lemma 3.6.** Let $\omega_3$ be the third component of the full vorticity $\mathbf{\omega} = \nabla \times \mathbf{V} = (\omega_1, \omega_2, \omega_3)$. Then, for any $0 < \delta_0 < 1$,

$$
\int_{V} |\text{curl}\, \zeta|^2 \, dV > \min\{1, 2(1 - \delta_0)\} \int_{V} |\nabla_2 \omega_3|^2 \, dV + 2\delta_0 \int_{V} \{|u_{yz}|^2 + |v_{xz}|^2\} \, dV 
+ \int_{V} \{|u_{zz}|^2 + |v_{zz}|^2 + \varepsilon^2(1 - \delta_0)|w_{zz}|^2\} \, dV. \quad (3.33)
$$

**Proof.** Using $\zeta$ in equation (2.9) in the form $\zeta = -v_z \mathbf{i} + u_z \mathbf{j} + \omega_3 \mathbf{k}$ with $\omega_3 = v_x - u_y$ and recalling that $\varepsilon w_z = -(u_x + v_y)$,

$$
\text{curl}\, \zeta = \begin{vmatrix} i & j & k \\ \partial_x & \partial_y & \partial_z \\ -v_z & u_z & \omega_3 \end{vmatrix} = \begin{vmatrix} i & \omega_3,y & -j \end{vmatrix}(\omega_3,y - u_{zz}) - j(\omega_3,x + v_{zz}) - \varepsilon k w_{zz}. \quad (3.34)
$$

Thus,

$$
|\text{curl}\, \zeta|^2 = |\nabla_2 \omega_3|^2 + (v_{zz}^2 + u_{zz}^2 + \varepsilon^2 w_{zz}^2) - 2(\omega_3,y u_{zz} - \omega_3,x v_{zz}). \quad (3.35)
$$

Now, invoking the boundary conditions and the fact that $\omega_3 = v_x - u_y$, integration by parts gives

$$
-2 \int_{V} (\omega_3,y u_{zz} - \omega_3,x v_{zz}) \, dV = 2 \int_{V} |\omega_{3,z}|^2 \, dV, \quad (3.36)
$$

and so

$$
\int_{V} |\text{curl}\, \zeta|^2 \, dV = \int_{V} |\nabla_2 \omega_3|^2 + 2|\omega_{3,z}|^2 \, dV + \int_{V} \left\{v_{zz}^2 + u_{zz}^2 + \varepsilon^2 w_{zz}^2\right\} \, dV. \quad (3.37)
$$

Moreover, it is easily shown that

$$
\int_{V} (\varepsilon^2 |w_{zz}|^2 + 2|\omega_{3,z}|^2) \, dV = \int_{V} \left\{(u_{xz} - v_{yz})^2 + 2(u_{yz}^2 + u_{xz}^2)\right\} \, dV 
> 2 \int_{V} (u_{yz}^2 + v_{xz}^2) \, dV, \quad (3.38)
$$

where a pair of horizontal integrations by parts in the first line of equation (3.38) have been performed. A linear combination of equations (3.37) and (3.38) gives

$$
\int_{V} |\text{curl}\, \zeta|^2 \, dV = \int_{V} \left\{|\nabla_2 \omega_3|^2 + 2|\omega_{3,z}|^2 \, dV\right\} + \int_{V} \left\{u_{zz}^2 + v_{zz}^2 + \varepsilon^2 w_{zz}^2\right\} \, dV 
> \int_{V} \left\{|\nabla_2 \omega_3|^2 + 2(1 - \delta_0)|\omega_{3,z}|^2 \, dV\right\}
+ \int_{V} \left\{u_{zz}^2 + v_{zz}^2 + (1 - \delta_0)\varepsilon^2 w_{zz}^2\right\} \, dV 
+ 2\delta_0 \int_{V} (u_{yz}^2 + v_{xz}^2) \, dV, \quad (3.39)
$$

which gives equation (3.33).
(ii) The evolution of \( \int_V |\Theta_z|^2 \, dV \)

The partial differential equation for \( \Theta \) given in equation (2.8) with boundary conditions applied on \( C(L, H) \),

\[
\frac{\partial \Theta}{\partial t} + V \cdot \nabla_3 \Theta = (\sigma Re)^{-1} \Delta_3 \Theta + q, \tag{3.40}
\]
is now differentiated with respect to \( z \), multiplied by \( \Theta_z \) and integrated to give

\[
\frac{1}{2} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV = (\sigma Re)^{-1} \int_V \Theta_z (\Delta_3 \Theta_z) \, dV - \int_V \Theta_z \frac{\partial}{\partial z} (V \cdot \nabla_3 \Theta) \, dV + \int_V \Theta_z q_z \, dV
\]

\[
= -(\sigma Re)^{-1} \int_V |\nabla_3 \Theta_z|^2 \, dV - \int_V V \cdot \nabla_3 \left( \frac{1}{2} \Theta_z^2 \right) \, dV
\]

\[
- \int_V \Theta_z (u_z \Theta_x + v_z \Theta_y + \varepsilon w_z \Theta_z) \, dV + \int_V \Theta_z q_z \, dV. \tag{3.41}
\]

However, given that \( \text{div} \, V = 0 \) and \( w = 0 \) on \( S^\pm \),

\[
\int_V V \cdot \nabla_3 \left( \frac{1}{2} \Theta_z^2 \right) \, dV = \int_V \left\{ \text{div} \left( \frac{1}{2} \Theta_z^2 V \right) - \frac{1}{2} \Theta_z^2 \text{div} \, V \right\} \, dV
\]

\[
= \frac{1}{2} \int_{S^\pm} (\hat{n} \cdot V) \Theta_z^2 \, dS
\]

\[
= \pm \frac{1}{2} \varepsilon \int_{S^\pm} w \Theta_z^2 \, dx \, dy = 0. \tag{3.42}
\]

Integrating by parts the third and fourth terms in equation (3.41) gives

\[
\frac{1}{2} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV = -(\sigma Re)^{-1} \int_V |\nabla_3 \Theta_z|^2 \, dV + \int_V \Theta_z (u_z \Theta_x + v_z \Theta_y + \varepsilon w_z \Theta_z) \Theta \, dV
\]

\[
+ \int_V \Theta (u_z \Theta_x + v_z \Theta_y + \varepsilon w_z \Theta_z) \, dV - \int_V \Theta_z q \, dV
\]

\[
= -(\sigma Re)^{-1} \int_V |\nabla_3 \Theta_z|^2 \, dV + \int_V \Theta (u_z \Theta_x + v_z \Theta_y + \varepsilon w_z \Theta_z) \, dV
\]

\[
- \int_V \Theta_z q \, dV, \tag{3.43}
\]

where \( \text{div} \, V = 0 \) has been used. Using a Hölder inequality, it is found that

\[
\frac{1}{2} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV \leq -(\sigma Re)^{-1} \int_V |\nabla_3 \Theta_z|^2 \, dV + ||\Theta_{zz}||_2 ||q||_2
\]

\[
+ ||\Theta||_6 (||u_z||_3 ||\Theta_{xz}||_2 + ||v_z||_3 ||\Theta_{yz}||_2 + \varepsilon ||w_z||_3 ||\Theta_{zz}||_2). \tag{3.44}
\]

The next task, addressed in the following lemma, is to estimate \( ||u_z||_3, ||v_z||_3 \) and \( ||w_z||_3 \) in terms of their second derivatives.
Lemma 3.7. With Neumann boundary conditions on $C(H,L)$, the vector $v_z$ and the scalar $w_z$ satisfy
\[ \|v_z\|_3 \leq \frac{6^{1/2}}{2} \|v_{zz}\| \|v\|_{6}^{1/2} \] (3.45)
and
\[ \|w_z\|_3 \leq \frac{12^{1/2}}{2} \|w_{zz}\| \|w\|_{6}^{1/2}. \] (3.46)

Proof.
\[ \int_V |v_z|^3 \, dV = \int_V (|u_z|^2 + |v_z|^2)^{3/2} \, dV \leq \frac{3}{2} \int_V (|u_z|^3 + |v_z|^3) \, dV, \] (3.47)
and, given the boundary conditions on $u$ and $v$,
\[ \int_V |u_z|^3 \, dV = \int_V u_z u_z |u_z| \, dV = \int_S \left\{ u u_{zz} |u_z| + u u_z \frac{d|u_z|}{dz} \right\} \, dx \, dy \leq 2 \int_V |u||u_{zz}||u_z| \, dV, \] (3.48)
which holds because $d|f|/dz \leq |f_z|$ for any appropriately differentiable function $f$. Thus, equation (3.47) becomes
\[ \int_V |v_z|^3 \, dV \leq 3 \int_V \{ |u||u_{zz}||u_z| + |v||v_{zz}||v_z| \} \, dV \leq 6 \int_V |v||v_{zz}||v_z| \, dV \leq 6 \|v\|_6 \|v_{zz}\|_2 \|v_z\|_3, \] (3.49)
which gives the advertised result. The result for $w$ follows in a similar manner. ■

Continuing with equation (3.44), multiplying by $Re^\gamma$, where $\gamma$ is to be determined, equation (3.44) becomes
\[
\frac{1}{2} \frac{d}{dt} Re^\gamma \int_V |\Theta_z|^2 \, dV \leq - (\sigma Re)^{-1} Re^\gamma \int_V |\nabla_\theta \Theta_z|^2 \, dV \\
+ 2^{1/2} Re^\gamma \|\Theta\|_6 \|w\|_{6}^{1/2} \|w_{zz}\|_2 \|\Theta_{zz}\|_2 \\
+ 6^{1/2} Re^\gamma \|v_{zz}\|_2 \|v\|_{6}^{1/2} \|\Theta\|_6 \|\Theta_{zz}\|_2 + \|\Theta_{zz}\|_2 \|q\|_2. \] (3.50)
In turn, this re-arranges to
\[
\frac{1}{2} \Re^{\gamma} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV \leq - (\sigma \Re)^{-1} \Re^{\gamma} \int_V |\nabla_3 \Theta_z|^2 \, dV
\]
\[
+ [4 \delta_3 \Re^{-1} e^2 \|w_{zz}\|_2^{2/2}]^{1/4} [\delta_3 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2]^{1/2}
\]
\[
\times [\delta_3^{-3} \sigma^2 \Re b^1 \|\Theta\|_6^{1/6}] [\delta_3^{-3} e^6 \sigma^2 \Re b^2 \|w\|_6^{1/12}]
\]
\[
+ ([4 \delta_4 \Re^{-1} \|v_{zz}\|_2]^{1/4} [3 \delta_4^{-3} \Re c^2 \|v\|_6^{1/12}]
\]
\[
\times \left[ \frac{\sigma^3}{8 \delta_4^3} \Re c^1 \|\Theta\|_6^{1/6} \right]^{1/6} [2 \delta_4 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2 + \|\Theta_{yzz}\|_2^2]^{1/2}
\]
\[
+ [\delta_5 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2]^{1/2} [\delta_5^{-1} (\sigma \Re) \Re^{\gamma} \|q\|_2^2]^{1/2},
\] (3.51)

where \( 2b_1 + b_2 = 9 + 6 \gamma \) and \( 2c_1 + c_2 = 9 + 6 \gamma \). Using Young's inequality, it is found that
\[
\frac{1}{2} \Re^{\gamma} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV \leq - (\sigma \Re)^{-1} \Re^{\gamma} \int_V |\nabla_3 \Theta_z|^2 \, dV
\]
\[
+ \delta_3 \Re^{-1} e^2 \|w_{zz}\|_2^2 + \frac{1}{2} \delta_3 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2
\]
\[
+ \frac{1}{6} \delta_3^{-3} \sigma^2 \Re b^1 \|\Theta\|_6^{1/6} + \frac{1}{12} \delta_3^{-3} e^6 \sigma^2 \Re b^2 \|w\|_6^6
\]
\[
+ \delta_4 \Re^{-1} \|v_{zz}\|_2^2 + \delta_4 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2 + \|\Theta_{yzz}\|_2^2
\]
\[
+ \frac{1}{48 \delta_4^3} \sigma^3 \Re c^1 \|\Theta\|_6^{1/6} + \frac{3 \delta_4^{-3} \Re c^2 \|v\|_6^6}{120 \delta_4^3}
\]
\[
+ \frac{1}{2} \delta_5 (\sigma \Re)^{-1} \Re^{\gamma} \|\Theta_{zz}\|_2^2 + \frac{1}{2} \delta_5^{-1} (\sigma \Re) \Re^{\gamma} \|q\|_2^2.
\] (3.52)

Gathering terms, we find
\[
\frac{1}{2} \Re^{\gamma} \frac{d}{dt} \int_V |\Theta_z|^2 \, dV \leq - (\sigma \Re)^{-1} \Re^{\gamma} \int_V \{(1 - \delta_4) (|\Theta_{zz}|^2 + |\Theta_{yzz}|^2)
\]
\[
+ \left( 1 - \frac{1}{2} \delta_3 - \frac{1}{2} \delta_5 \right) |\Theta_{zz}|^2 \} \, dV
\]
\[
+ \Re^{-1} \{ \delta_4 \|v_{zz}\|_2^2 + \delta_3 e^2 \|w_{zz}\|_2^2 \} + \frac{3 \delta_4^{-3} \Re c^2 \|v\|_6^6}{120 \delta_4^3}
\]
\[
+ \left\{ \frac{\sigma^2}{6 \delta_4^3} \Re b^1 + \frac{\sigma^3}{48 \delta_4^3} \Re c^1 \right\} \|\Theta\|_6^{1/6} + \frac{e^6 \sigma^2}{120 \delta_4^3} \Re b^2 \|w\|_6^6
\]
\[
+ \frac{1}{2} \delta_5^{-1} (\sigma \Re) \Re^{\gamma} \|q\|_2^2.
\] (3.53)

*Phil. Trans. R. Soc. A (2011)*
(iii) A combination of the fluid and temperature inequalities

Equation (3.53) is now combined with equation (3.32)

\[
\frac{1}{2} \left( 1 - \frac{3}{4} \delta_1 - \delta_2 \right) \frac{d}{dt} \left( \int \mathcal{V} |\xi|^2 dV + \frac{1}{2} Re^{\gamma} \frac{d}{dt} \int \mathcal{V} |\Theta|^2 dV \right) \\
\leq - \left( 1 - \frac{3}{4} \delta_1 - \delta_2 \right) Re^{-1} \int \mathcal{V} |\text{curl} \xi|^2 dV \\
- (\sigma Re)^{-1} Re^{\gamma} \int \mathcal{V} \left\{ (1 - \delta_4) (|\Theta_{xx}|^2 + |\Theta_{yy}|^2) + \left( 1 - \frac{1}{2} \delta_3 - \frac{1}{2} \delta_5 \right) |\Theta_{zz}|^2 \right\} dV \\
+ Re^{-1} (\delta_4 \|v_{zz}\|^2 + \delta_3 \varepsilon^2 \|w_{zz}\|^2) + \left( \frac{9}{4 \delta_1^3} Re^3 + \frac{3^6}{12 \delta_1^3} Re^{\varepsilon^2} \right) \|v\|_6^6 \\
+ \varepsilon^6 \left( \frac{3}{2 \delta_1^3} Re^3 + \frac{\sigma^2}{12 \delta_1^3} Re^{b_2} \right) \|w\|_6^6 + \left( \frac{\sigma^2}{6 \delta_1^3} Re^{b_1} + \frac{\sigma^3}{48 \delta_1^3} Re^{c_1} \right) \|\Theta\|_6^6 \\
+ \frac{1}{\varepsilon^2} \left( \delta_2 + \frac{1}{2 \delta_2} \right) Re \|v\|_2^2 + \frac{9^6}{2 \varepsilon^2 \delta_2} Re \|\Theta\|_2^2 + \frac{1}{2} \delta_5^{-1} (\sigma Re) Re^{\gamma} \|q\|_2^2.
\]

where

\[
2b_1 + b_2 \\
2c_1 + c_2 = 9 + 6\gamma.
\]

Our choices are

\[
b_1 = c_1 = -3, \quad b_2 = c_2 = 3 \quad \text{and} \quad \gamma = -2.
\]

\(\delta_3\) and \(\delta_4\) also need to be chosen such that the \(\|v_{zz}\|^2\) and \(\varepsilon^2 \|w_{zz}\|^2\) terms cancel from \(\|\text{curl} \xi\|_2^2\). To this end, we choose \(\delta_0 = 1/2\), and make

\[
1 - \frac{3}{4} \delta_1 - \delta_2 = \delta_4
\]

and

\[
\left( 1 - \frac{3}{4} \delta_1 - \delta_2 \right) (1 - \delta_0) = \delta_3.
\]

Hence, \(\delta_1 = 2\delta_3\). With this, we choose \(\delta_5\) such that the coefficients \(1 - \delta_4\) and \(1 - 1/2\delta_3 - 1/2\delta_5\) within the double derivatives of the temperature are equal. Thus, \(\delta_5 = 3\delta_3\). Together, we have

\[
\delta_3 = \frac{1}{2} \left( 1 - \frac{3}{4} \delta_1 - \delta_2 \right), \quad \delta_4 = 2\delta_3 \quad \text{and} \quad \delta_5 = 3\delta_3.
\]

where \(\delta_1 > 0\) and \(\delta_2 > 0\) are arbitrarily chosen under the constraint that \(\delta_3 > 0\).

Now we turn to the last three steps in the calculation.

Step 1. To deal with the first set of terms on the right-hand side of equation (3.54), we use the expression for \(\|\text{curl} \xi\|_2^2\) in lemma 3.6 with \(\delta_0 = 1/2\) and write

\[
\int_{\mathcal{V}} |\text{curl} \xi|^2 dV - \left( \|v_{zz}\|_2^2 + \frac{1}{2} \varepsilon^2 \|w_{zz}\|_2^2 \right) \geq \int_{\mathcal{V}} \{ |\nabla_2 \omega_3|^2 + |u_{yz}|^2 + |v_{xz}|^2 \} dV.
\]

\(\text{Phil. Trans. R. Soc. A} (2011)\)
This turns equation (3.54) into
\[
\frac{1}{2} \frac{d}{dt} \int_V \left| \xi \right|^2 dV + \frac{1}{2} \Re^{-2} \frac{d}{dt} \int_V \left| \Theta z \right|^2 dV
\leq -2\delta_3 \Re^{-1} \int_V \left\{ \left| \nabla_2 \omega_3 \right|^2 + \left| u_{xz} \right|^2 + \left| u_{xz} \right|^2 \right\} dV
- \sigma^{-1} (1 - 2\delta_3) \Re^{-3} \int_V \left| \nabla_3 \Theta \right|^2 dV + \left( \frac{9}{4\delta_1^3} + \frac{243}{32\delta_3^3} \right) \Re^3 \| \nu \|_6^6
+ \epsilon^6 \left( \frac{3}{2\delta_1^3} + \frac{\sigma^2}{12\delta_3^3} \right) \Re^3 \| w \|_6^6 + \frac{\sigma^2}{6\delta_3^3} \left( 1 + \frac{\sigma}{64} \right) \Re^{-3} \| \Theta \|_6^6
+ \epsilon^{-2} \Re \left\{ \left( \delta_2 + \frac{1}{2\delta_2} \right) \| \nu \|_2^2 + \frac{\alpha_0^2}{2\delta_2} \| \Theta \|_2^2 \right\} + \frac{\sigma}{6\delta_3} \Re^{-1} \| q \|_2^2.
\] (3.60)

Step 2. Now this inequality is re-scaled back to dimensional variables defined in table 2 and \( \mathcal{H}(t) \) defined in equation (3.3). This involves multiplying both sides of equation (3.60) by \( \Re^3 \),
\[
\frac{1}{2} \frac{d}{dt} \mathcal{H} \leq -2\delta_3 \Re^{2} \int_V \left( \left| \nabla_2 \Omega_3 \right|^2 + \alpha_a^2 \left| u_{1,2,2,3} \right|^2 + \alpha_a^2 \left| u_{2,1,2} \right|^2 \right) dV
- \left( \frac{1 - 2\delta_3}{\sigma T_0^2} \right) \int_V \left| \nabla T_{x3} \right|^2 dV
+ \left( \frac{9}{4\delta_1^3} + \frac{243}{32\delta_3^3} \right) \| \mathcal{R}_{u_{hor}} \|_6^6 + \left( \frac{3}{2\delta_1^3} + \frac{\sigma^2}{12\delta_3^3} \right) \| \mathcal{R}_{u_3} \|_6^6
+ \frac{\alpha_a^2 \sigma^2}{6\delta_3^3} \left( 1 + \frac{\sigma}{64} \right) \| \mathcal{R}_{a,T} \|_6^6
+ \epsilon^{-2} \left\{ \left( \delta_2 + \frac{1}{2\delta_2} \right) \Re^2 \| \mathcal{R}_{u_1} \|_2^2 + \frac{\alpha_0^2 \sigma^{-6}}{2\delta_2} \Re^4 \| \mathcal{R}_{a,T} \|_2^2 \right\}
+ \frac{\sigma}{6\delta_3} \Re \| q \|_2^2.
\] (3.61)

Step 3. Finally, we take the time integral over an interval \([0, \tau_*]\),
\[
\int_0^{\tau_\ast} \int_V \left\{ -\frac{2\delta_3 \Re^{2} \left| \nabla_2 \Omega_3 \right|^2 + \alpha_a^2 \left| u_{1,2,2,3} \right|^2 + \alpha_a^2 \left| u_{2,1,2} \right|^2 \right\} - \frac{1 - 2\delta_3}{\sigma T_0^2} \left| \nabla T_{x3} \right|^2
+ \beta_{u_{hor}} \| \mathcal{R}_{u_{hor}} \|_6^6 + \beta_{u_3} \| \mathcal{R}_{u_3} \|_6^6 + \beta_{1,T} \| \mathcal{R}_{a,T} \|_6^6 + \beta_{2,T} \Re^4 \| \mathcal{R}_{a,T} \|_2^2 + F_{11}(Q)
+ \frac{1}{2} \mathcal{V}_\ast^{-1} \mathcal{H}(0) \right\} dV dt \geq \frac{1}{2} \mathcal{H}(\tau_\ast).
\] (3.62)

Because of regularity \([28–31], \mathcal{H}(\tau_\ast) \) is always under control from above, and it also has a uniform lower bound \( \mathcal{H}(\tau_\ast) > 0 \), although zero may be a poor lower bound.

Phil. Trans. R. Soc. A (2011)
Theorem 3.1 follows from the use of lemma 3.6 with the choice \( \delta_0 = 1/2 \). \( \beta_{u_{\text{hor}}} \), \( \beta_{u_3} \) and \( \beta_{a,T} \) are defined in table 3 and the forcing function \( F_H(Q) \) is defined in equation (3.2).

4. Potential implications for simulations

The main result of this paper is that solutions of HPEs can potentially develop extremely small scales of motion, allowed by the estimates derived here. These size scales decrease as \( R_u^{-1} \) and \( R_{a,T}^{-1} \), which means they could easily become of the order of metres or less at the very large values of these parameters achieved in both atmospheric and oceanic flows. The hydrostatic estimate for the length scale defined \( \lambda_H \) in equation (3.7) is of the order of a metre or less. Of course, this very small estimate may not be the thickness of a front; instead, it may refer to the smallest scale of features within a front. The importance of the tendency to produce vigorous intermittent small scales in NWP and ocean circulation simulations remains to be determined, but it may affect parametrizations as numerical resolution improves. In particular, one may ask whether parametrizations developed at coarser scales will still be accurate at finer scales, if the finer scales undergo the extreme events whose potential appearance has been predicted in this paper. As for the perennial question of initial conditions, one must hope that flow activity initialized at coarse scales will be consistently followed to smaller scales without undue amplification of simulation errors.

The consequence of theorem 3.1 in §3 is that space–time is potentially divided into two regions \( S^+ \) and \( S^- \). The region \( S^- \) could be a union of a large number of disjoint sets, and if it were non-empty, the flows in \( S^- \) would be dominated by strong concentrated structures. Very large lower bounds on double-mixed derivatives of components of the velocity field \((u_1, u_2, u_3)\) such as \(|\partial^2 u_1/\partial x_2 \partial x_3|^2\) or \(|\partial^2 u_2/\partial x_1 \partial x_3|^2\) may occur within \( S^- \), thus representing intense accumulation in the \((x_1, x_3)\)- and \((x_2, x_3)\)-planes, respectively. For a non-empty \( S^- \), one would see the spontaneous formation of front-like objects localized in space that would only exist for a finite time. \( R_{u_{\text{hor}}} \) is a local horizontal Reynolds number depending upon the local space–time values of \( u(x_1, x_2, x_3, \tau) = (u_1^2 + u_2^2)^{1/2} \) and \( R_{a,T} \) is a Rayleigh number dependent on the local temperature \( \bar{T}(x_1, x_2, x_3, \tau) \). The large lower bounds on double derivatives of solutions within the \( S^- \) regions can be converted into the large lower bounds on inverse length scales \( \lambda_H^{-1} \). Thus, to resolve a region such as this would require:

$$\text{Number of grid points} > \text{const. } (R_{u_{\text{hor}}}^3 + R_{a,T}^3 + ReR_{a,T})$$

(4.1)

It is also worth remarking that the \( L^6 \)-norm arising in the proof of theorem 3.1, leading to the sixth powers of the local Reynolds numbers \( R_{u_{\text{hor}}} \) for \( \lambda_H^{-1} \), is precisely the norm that was proved by Cao & Titi [28,29] to be bounded for the HPE. While \( R_{u_{\text{hor}}} \) is a function of space–time, it is a bounded function, but how much \( R_{u_{\text{hor}}} \) oscillates around its global space–time average \( Re \) is unknown; this could vary significantly in different parts of the flow. Thus, how \( u_3 = \{u_1, u_2, u_3\} \) varies across a front is an important issue. The limitations of the result are that \( R_{u_3} \) is expected to be negligible compared with \( R_{u_{\text{hor}}} \) because \( u_3 \sim O(\epsilon) \).

Phil. Trans. R. Soc. A (2011)
no further information is available from the analysis regarding the spatial or temporal statistics of the subsets of $S^{-}$ on which intense events would occur.

If the regularity problem were to be settled in the NPE case, the results would probably be qualitatively the same, but with a non-negligible $R_{w_3}$ term whose contribution might be significant in regions of strong vertical convection. There would also have to be significant technical differences: the domain would need to be made periodic in the velocity variables and their derivatives, because of lack of specification of horizontal velocity derivatives.

Future improvements in numerical capabilities for the prediction of weather, climate and ocean circulation may be expected to enhance spatial and temporal resolutions. In addition, they will raise the issue of the optimal allocation of numerical resources. For example, improving the computations for parametrizations of other currently unresolved physical processes (such as phase changes in cloud physics) may have effects that are at least as significant as computing non-hydrostatic effects at finer resolution. Improvements in resolution will also raise the issue of whether subgrid-scale parametrizations of these unresolved physical processes that have been developed for numerical prediction at coarser scales will transfer accurately to computations at finer scales, regardless of whether the hydrostatic approximation is retained. Thus, one may expect the HPE to remain central in the discussions about choices among the various potential numerical-code implementations for weather, climate and ocean-circulation predictions well into the foreseeable future. Even though they are mathematically well posed, the HPEs have been shown here to contain the potential for sudden, localized events to occur on extremely small scales in space and time.

We thank Peter Bartello, Raymond Hide, Brian Hoskins, Tim Palmer and Edriss Titi for several enlightening conversations. D.H. thanks the Royal Society for a Wolfson Research Merit Award.
